

THE SUN AS BOREXINO SEES IT IN REAL TIME

INSIDE THE SUN

NEUTRINOS

Neutrinos are particles with no electric charge and a tiny mass. They rarely interact with matter and may cross it undisturbed. That's why they take 8 minutes to get there from the core of the Sun to the Earth.

PHOTONS

The radiation studied so far is made up of photons, which interact with solar matter. It takes about 100.000 years for it to reach the Sun's surface and reach Earth.

8 minutes

100.000 years

Gran Sasso

1,4 km of rock

By analyzing P-P neutrino emission, Borexino has shown that the energy produced today in the Sun's core is equal to that produced 100.000 years ago.

THE BOREXINO DETECTOR: HOW IT WORKS

Stainless steel sphere
13,7 m diameter

Thin nylon film
(radon gas barrier)

Nylon sphere
8,5 m diameter

Shielding
steel dishes

Muons detector:
200 photomultiplier tubes
(facing outwards)

Vessel retention ropes

2.200 photomultiplier tubes
(facing inwards)

300 tons
organic liquid scintillator

Stainless steel
water tank
18 m diameter

THE THERMONUCLEAR FUSION REACTION THAT PRODUCES THE P-P NEUTRINOS RECENTLY STUDIED BY BOREXINO

Borexino displays a russian doll structure. Surrounded by 2.400 tons of highly purified water, a stainless steel sphere contains 1.000 tons of a liquid hydrocarbon (pseudocumene). At its center, within a smaller nylon sphere, are 300 tons of scintillating liquid.

Within this innermost sphere neutrinos interact with the liquid scintillator producing small flashes of light.

The photomultiplier tubes, acting as ultra-sensitive artificial eyes, detect and record the light flashes produced by the neutrinos. Borexino observes dozens of these signals every day.
